### Introduction

Methanol plays an important role as basic chemical compound, a kind of transportation fuel and source of hydrogen for fuel cells. Industrially, methanol is produced from synthesis gas  $\text{CO}/\text{CO}_2/\text{H}_2$  under high temperature and high pressure conditions. The most known catalysts for methanol synthesis are copper/zinc based oxide catalyst [1]. For these catalysts the linear relationship between the catalytic activity and the metallic copper area was observed. Additionally, the methanol synthesis occurred exclusively on the surface of metallic copper. The catalytic activity of methanol synthesis from  $\text{CO}_2/\text{H}_2$  on the  $\text{Cu}/\text{ZnO}/\text{Al}_2\text{O}_3$  catalyst showed the maximum yield of methanol formation correlated with growth of the metallic copper surface area and  $\text{Cu}/\text{ZnO}$  molar ratio being about 8 [2]. Additionally  $\text{Cu}/\text{ZnO}$  - based catalysts are used for other catalytic reactions such as water gas shift reaction WGS [3], the methanol steam reforming and synthesis of higher alcohols.

### Materials and Methods

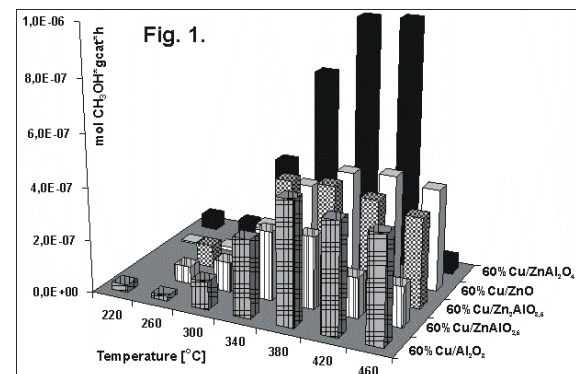

In the present work copper supported catalysts ( $\text{Cu}/\text{ZnAl}_2\text{O}_4$ ,  $\text{Cu}/\text{ZnAlO}_{2.5}$ ,  $\text{Zn}_2\text{AlO}_{3.5}$ ,  $\text{Cu}/\text{Al}_2\text{O}_3$ ,  $\text{Cu}/\text{ZnO}$ ) were prepared by conventional impregnation methods and there were examined their physicochemical properties (surface area and porosity, reduction behavior, phase composition) and the catalytic performance in carbon dioxide hydrogenation to methanol.

### Results and Discussion

The investigation of the influence of composition of binary oxide  $\text{ZnAl}_2\text{O}_4$ ,  $\text{ZnAlO}_{2.5}$ ,  $\text{Zn}_2\text{AlO}_{3.5}$  on their activity and physicochemical properties of copper catalysts in methanol synthesis was the main goal of this work. We confirmed that reduction and activity of copper supported catalysts depends strongly on copper loading and support composition. For copper (60% wt.) catalysts supported on various supports calcined at  $400^\circ\text{C}$  two reduction steps were observed and attributed to copper oxide reduction  $\text{CuO} \rightarrow \text{Cu}_2\text{O} \rightarrow \text{Cu}$ . The same shape of TPR curves have copper catalysts calcined at  $700^\circ\text{C}$  supported on various oxides:  $\text{ZnO}$ ,  $\text{ZnAlO}_{2.5}$  and  $\text{Zn}_2\text{AlO}_{3.5}$ . Three reduction effects observed in the case of 60% $\text{Cu}/\text{ZnAl}_2\text{O}_4$  and 60% $\text{Cu}/\text{Al}_2\text{O}_3$  catalysts calcined at  $700^\circ\text{C}$  are assigned to copper oxide and spinel  $\text{CuAl}_2\text{O}_4$  reduction. XRD results confirmed for 60% $\text{Cu}/\text{ZnAl}_2\text{O}_4$  supported catalyst the presence of following oxidic phases:  $\text{ZnO}$ ,  $\text{CuO}$  and  $\text{ZnAl}_2\text{O}_4$ . On the contrary XRD analysis of 60% $\text{Cu}/\text{Al}_2\text{O}_3$  shows the presence of  $\gamma\text{-Al}_2\text{O}_3$ ,  $\text{CuO}$  and  $\text{CuAl}_2\text{O}_4$  phases and  $\text{ZnO}$ ,  $\text{CuO}$  oxidic phases in the case of 60% $\text{Cu}/\text{ZnO}$  catalyst. The temperature characteristics of catalytic activity of copper supported catalysts in hydrogenation of  $\text{CO}_2$  expressed in  $\text{mol CH}_3\text{OH g}^{-1}_{\text{cat}} \text{h}^{-1}$  are presented in Fig. 1. Activity tests in methanol synthesis show that the most suitable support for

methanol formation was spinel type  $\text{ZnAl}_2\text{O}_4$  system, what can be explained by fact that this bixide have the most stabilizing effect on the copper ions present on the catalyst surface. TPD- $\text{CO}_2$  measurements showed that  $\text{ZnAl}_2\text{O}_4$  system adsorbed the largest amount of  $\text{CO}_2$  on the catalysts surface, what can explained high activity of 60% $\text{Cu}/\text{ZnAl}_2\text{O}_4$  catalyst in methanol formation (see Fig. 1).

**Figure 1.** Catalytic activity in methanol synthesis for copper catalysts supported on different supports.

### Significance

1. The calcination temperature and composition of catalyst strongly influence on reduction behavior of copper supported catalysts. Only for catalysts with high aluminum content and after its calcination at  $700^\circ\text{C}$  high temperature reduction effects were observed originating from  $\text{CuAl}_2\text{O}_4$  spinel phase reduction.
2. XRD results confirmed the presence of  $\text{CuAl}_2\text{O}_4$  spinel phase in the case of  $\text{Cu}/\text{Al}_2\text{O}_3$  catalyst and presence of this phase can not be ruled out for catalysts supported on binary oxides.
3. The catalytic activity depends strongly on support composition.
4. The most active was 60% $\text{Cu}/\text{ZnAl}_2\text{O}_4$  catalyst exhibiting largest uptake of  $\text{CO}_2$  in low temperature range.
